**Abstract.** 4-(Thiophen-2-yl)butanoic acid was identified as a cyclic substitute of the unsaturated alkyl chain of the natural ligand, capsaicin. Accordingly, a new class of amides was synthesized in good yield and high purity and their molecular recognition against the target was investigated by means of docking experiments followed by molecular dynamics simulations, in order to rationalize their geometrical and thermodynamic profiles. The pharmacological properties of these new compounds were expressed as activation ( $EC_{50}$ ) and desensitization ( $IC_{50}$ ) potencies. Several compounds were found to activate TRPV1 channels, and in particular, derivatives **1** and **10** behaved as TRPV1 agonists endowed with good efficacy as compared to capsaicin. The most promising compound **1** was also evaluated for its protective role against oxidative stress on keratinocytes and differentiated human neuroblastoma cell lines expressing the TRPV1 receptor as well as for its cytotoxicity and analgesic activity *in vivo*.

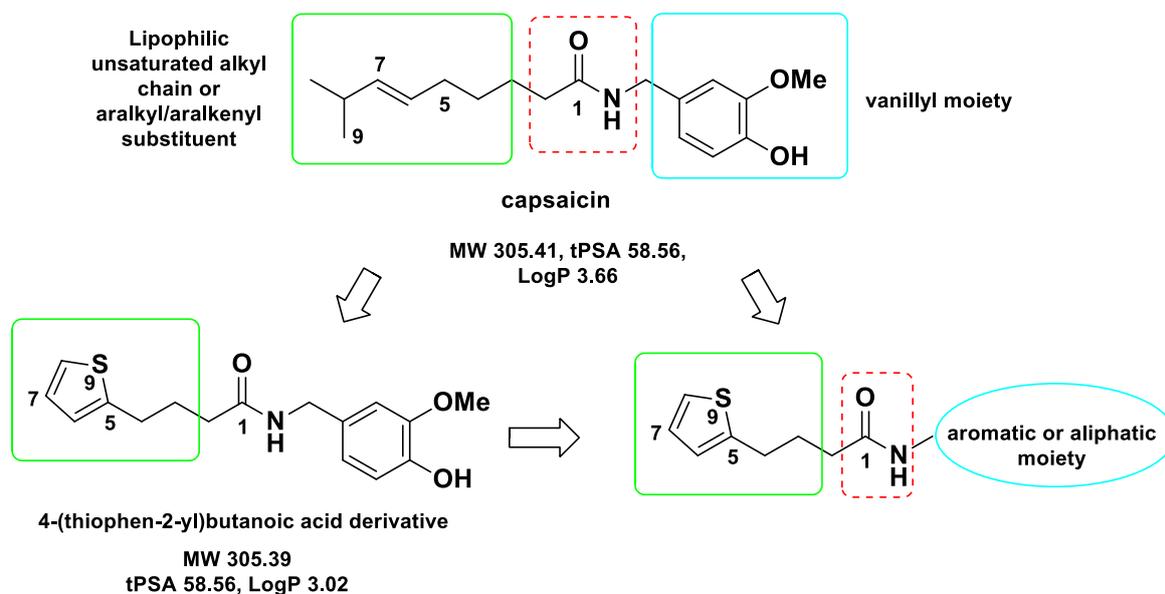

### **Keywords**

TRPV1 ligands, capsaicin, antioxidant, oxidative stress, neuroprotective, antinociceptive.

## INTRODUCTION

The TRPV1 is a non-selective cation channel with high  $\text{Ca}^{2+}$  permeability, abundantly expressed in sensory neurons and in higher brain structures, involved in pain processing and neurogenic inflammatory response. In fact, TRPV1 is a polymodal nociceptor up-regulated during chronic pain conditions and exhibits a dynamic threshold of activation that could be significantly lowered by inflammatory conditions such as mild acidification, temperatures over 43 °C and various, mostly noxious, natural products.<sup>1</sup> Among these, the natural pungent principle capsaicin was the first TRPV1 agonist described and its potential analgesic effects were known long before to the identification of its receptor.<sup>2</sup> Capsaicin (*trans*-8-methyl-*N*-vanillyl-6-nonenamide) is a crystalline, lipophilic, colourless and odourless compound found primarily in the *Capsicum* fruit,<sup>3</sup> responsible of its spicy flavour. Its action is unique in that the initial stimulation of the receptor is followed by a lasting refractory state, traditionally termed desensitization, silencing the whole nerve terminal.<sup>4</sup> However, capsaicin's pungency limits its use in clinical trials, so that the characterization and extraction/synthesis of non-pungent analogues is still in progress. Available experimental evidences indicate that vanilloid agonists, exerting their antinociceptive actions through TRPV1 receptor-mediated selective neurotoxic/neurodegenerative effects directed against somatic and visceral C-fibre nociceptive primary afferent fibres, might be part of analgesic drugs which do not cause addiction and tachyphylaxis.<sup>5</sup> Hence, TRPV1 channels have become a promising pain relief drug target, representing the key mediator in pain processing and neurogenic inflammatory response,<sup>6</sup> and have opened the door for development of new type of analgesics. Nevertheless, capsaicin and related compounds, called capsaicinoids, display a broad spectrum of pharmacological and physiological actions only in part receptor-dependent. Their antioxidant properties, owing to some structural requirements (vanillyl substitution pattern) for free radical-scavenging activity,<sup>7</sup> also contribute to the beneficial effects exhibited by these natural compounds,<sup>8</sup> and a wide range of pathological conditions may benefit from capsaicin-derived agents, such as cancer, inflammation, and cardiovascular diseases.

The structure of capsaicin provided the basis for developing structure-activity relationship for small-molecule TRPV1 modulators, both agonists and antagonists. Three structural features have been identified as critical for receptor interaction as shown in the Figure 1. The lipophilic moiety (nonyl chain for capsaicin), replaceable by an alkyl/alkenyl chain maybe bringing a terminal aromatic nucleus,<sup>9</sup> the polar head (3-methoxy-4-hydroxybenzyl portion), and the linker (an amide for capsaicin, an ester for resiniferatoxin).<sup>10</sup> Both H-bond donor/acceptor aromatic substituents on the vanillyl moiety are important for a potent agonist activity and, in particular, the 4-phenolic hydroxy group represents a crucial pharmacophoric element,<sup>9</sup> while the lipophilicity is relevant for the bioactivity, since TRPV1 agonists need to cross the cell membrane to reach their target.<sup>11</sup>

**Figure 1.** Critical chemical features and general structure of the new synthesized compounds

The aim of this study was to design and synthesize a novel class of TRPV1 ligands endowed with potential agonist or antagonist activity and characterized by a 4-(thiophen-2-yl)butanoic acid amide moiety instead of the nonenoyl chain of capsaicin. In fact, capsaicin is a moderately flexible molecule characterized by a double bond, whose geometry (*trans* in the natural compound, *cis* in the synthetic derivative civamide)<sup>12</sup> does not seem crucial for receptor interaction. Moreover, several studies<sup>13</sup> suggest that the side chain of capsaicin interacts with the receptor in a linear and extended

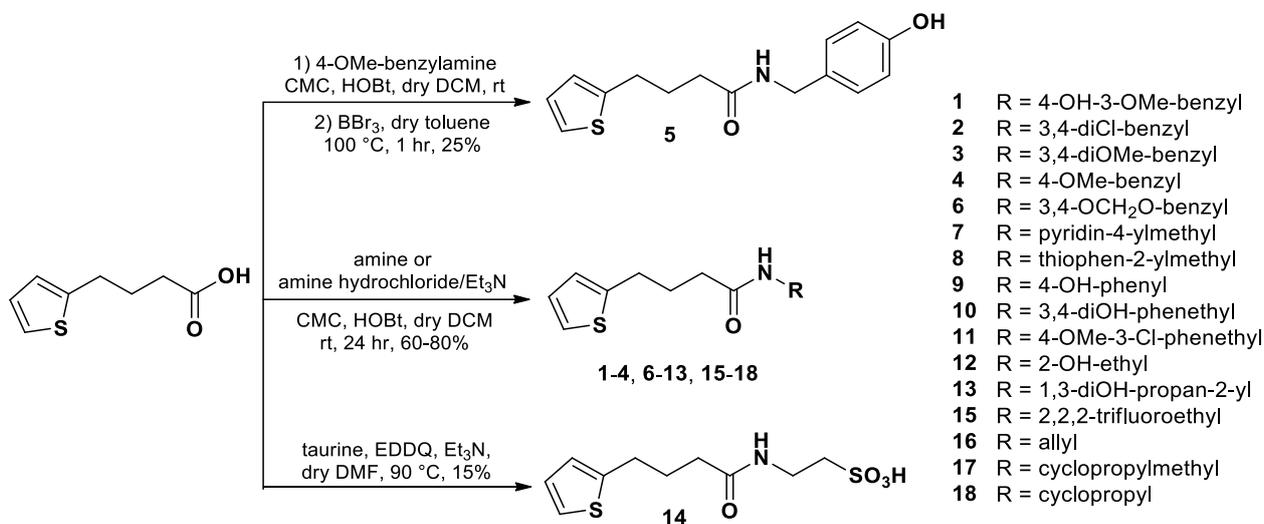

conformation. Therefore, the 4-(thiophen-2-yl)butanoic acid has been considered as suitable cyclic substitute of the unsaturated alkyl chain of the natural compound, because it is chemically characterized by an equivalent number of atoms organized in a short but flexible alkyl chain bearing a heteroaryl nucleus. Interestingly, both capsaicin and derivatives we designed show identical molecular weight, and similar coefficient partition (logP) and topological polar surface area (tPSA) values (Figure 1), thus underlining potentially similar physicochemical and binding properties. Moreover, in the attempt to investigate the influence of the polar head on biological activity and how the electronic/steric properties of this moiety can affect receptor interaction, a family of new derivatives, characterized by high chemical diversity at the polar end, has been synthesized. The present paper describes the functional TRPV1 activities of the designed new ligands and their structure-activity relationship (SAR) analysis. A molecular modelling analysis, carried out by means of docking and molecular dynamics simulations, allowed to investigate the binding modes of the synthesized ligands against TRPV1 target, indicating compound **1** as the most theoretically promising. For such a compound, herein, we report the results of a wider biological evaluation, including cytotoxicity and viability behaviour, its protective role against oxidative stress on HaCaT cells (keratinocytes) and on differentiated human neuroblastoma IMR-32 cell line expressing TRPV1 receptors, and finally, its *in vivo* analgesic activity.

## **RESULTS AND DISCUSSION**

### **Chemistry**

According to the aforementioned structural requirements, a series of selected aromatic and aliphatic amines were condensed with 4-(thiophen-2-yl)butanoic acid, following different synthetic procedures, as depicted in Scheme 1. Besides vanillyl moiety, several aromatic/heteroaromatic, benzyl and phenethyl amines were selected, some of which characterized by a 4-phenolic hydroxy group (i.e. 4-hydroxyaniline, 4-hydroxybenzylamine, and 3-hydroxytyramine) or by polar substituents (i.e. methoxy and/or chloro, 3,4-methylenedioxy groups), while the introduction of

aliphatic amines was pursued in order to obtain derivatives with different H-bond donor/acceptor properties as well as a variable degree of lipophilicity.

**Scheme 1.** Synthetic pathways to obtain the designed amides **1-18**

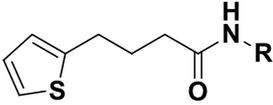

Commercial 4-(thiophen-2-yl)butanoic acid was coupled in dichloromethane as solvent with the appropriate commercial amines in the presence of 1-cyclohexyl-3-(2-morpholinoethyl)carbodiimide (CMC) and 1-hydroxybenzotriazole (HOBT) to give the final amides **1-4**, **6-13** and **15-18** (yields ranging from 60% to 80%). Demethylation reaction in the crude amide **4** was performed with BBr<sub>3</sub> in refluxing dry toluene, furnishing the desired amide **5**. Alternatively, the coupling between the 4-(thiophen-2-yl)butanoic acid and taurine was achieved using a different activating agent, the N-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline (EDDQ), in dry DMF, to give the final amide **14** with an acceptable yield of 15%.

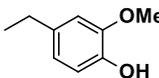

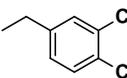

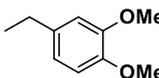

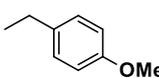

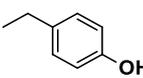

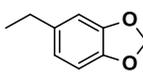

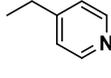

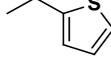

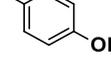

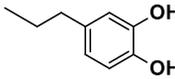

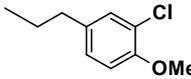

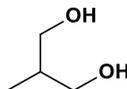

### **In vitro and in vivo pharmacology**

Amides **1-18**, and natural agonist capsaicin, were evaluated for their pharmacological behaviour against TRPV1 receptors by a functional assay using human embryonic kidney (HEK293) cells stably over-expressing recombinant human TRPV1.<sup>14</sup> The increase concentration of intracellular calcium was used as a measure of the two effects, and activation (EC<sub>50</sub>) and desensitization (IC<sub>50</sub>, determined against the effect of capsaicin after a 5 mins pre-incubation with each compound) potency values

were summarized in Table 1 (For concentration-effect curves used to generate EC<sub>50</sub> and IC<sub>50</sub> values of compound **1** see Figures S5 and S6 of the Supporting Information).

<sup>a</sup>Data are means ± SEM of  $N = 3$  determinations. <sup>b</sup>As percent of the effect of ionomycin (4  $\mu\text{M}$ ). <sup>c</sup>Determined against the effect of capsaicin (0.1  $\mu\text{M}$ ) after a 5 mins pre-incubation with each compound. <sup>d</sup>n.a. = not active.

To establish the biological profile of the most interesting TRPV1 ligand **1**, cytotoxicity and viability were evaluated in keratinocytes (HaCaT),<sup>15</sup> by cellular LDH release and Alamar Blue assay respectively, after treatment with the TRPV1 ligand **1** or capsaicin, as reference compound, at concentrations ranging from 0.1 to 10  $\mu\text{M}$  at 24 and 48 hs (Figure 2).

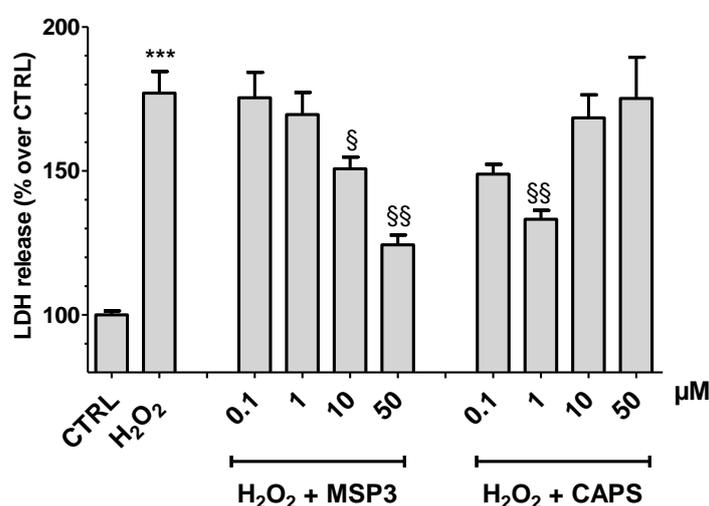

**Figure 2.** Cytotoxicity of compound **1** (MSP-3; A and B) and capsaicin (C and D) after 24 hs and 48 hs incubation at concentrations ranging from 0.1 to 10  $\mu$ M in HaCaT cell line. A and C) LDH release assay and B and D) Alamar Blu assay. Data are expressed as mean  $\pm$  SEM (n = 5). No significant difference was observed between groups (One way ANOVA with Bonferroni post hoc test).

The protective role of the same compound against oxidative stress was investigated on two cell lines, in HaCaT cells and differentiated human neuroblastoma IMR-32 cells, expressing TRPV1 receptors. HaCaT cells<sup>16</sup> were treated with glucose oxidase (GO) for 1 h to allow the generation of hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) as source of oxidative stress (OS). A consequence of OS is the induction of lipid peroxidation that generates several lipid oxidation products (LOPs) among which the unsaturated aldehyde 4-hydroxy-2-nonenal (HNE) is one of the most reactive and potentially toxic. Therefore, evaluating the formation of HNE protein-adducts in keratinocytes pre-treated or not pre-treated with compound **1** or capsaicin, can give an indirect measurement of the “antioxidant” properties of the compounds (Figure 3).<sup>17</sup>

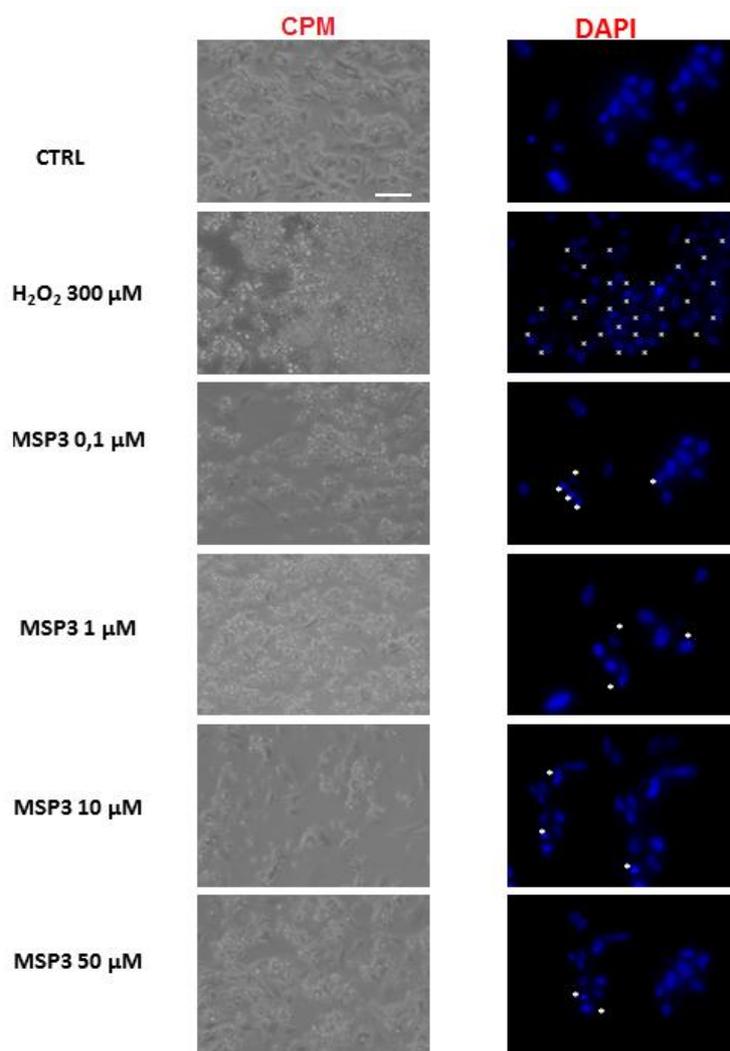

**Figure 3.** HNE protein-adducts induced by GO treatment in HaCaT cells, measured by Western blot. Data are representative of three experiments. Cells were pre-treated with compound **1** (MSP-3) or with capsaicin for 24 hs and then treated with GO for 1 h. Quantifications of HNE protein-adduct bands is shown as ratio of HNE/ $\beta$ -actin (bottom panel). Data are expressed as arbitrary units (mean  $\pm$  SEM, n = 3); statistical analysis was performed by one way ANOVA followed by Bonferroni post hoc test; \* P < 0.05 vs control; # P < 0.05 vs GO.

IMR-32 cells were differentiated<sup>18</sup> and then hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>, 300 μM for 15 hs) was used as neurotoxin producing OS resulting in cell death. To assess neuroprotective effects, differentiated neuroblastoma cells expressing TRPV1 receptors<sup>19</sup> were pre-treated with test compound **1** or with capsaicin (used as reference compound) at concentrations ranging from 0.1 to 50 μM, and cellular LDH release determined in medium at the end of the experiment (Figure 4). Cell morphology analysis (phase-contrast light microscope) and apoptosis-mediated cell death based on nuclear staining with 4',6-diamidino-2-phenylindole (DAPI) fluorescent probe (Figure 5) were also performed to further investigate compound **1**-mediated neuroprotection.

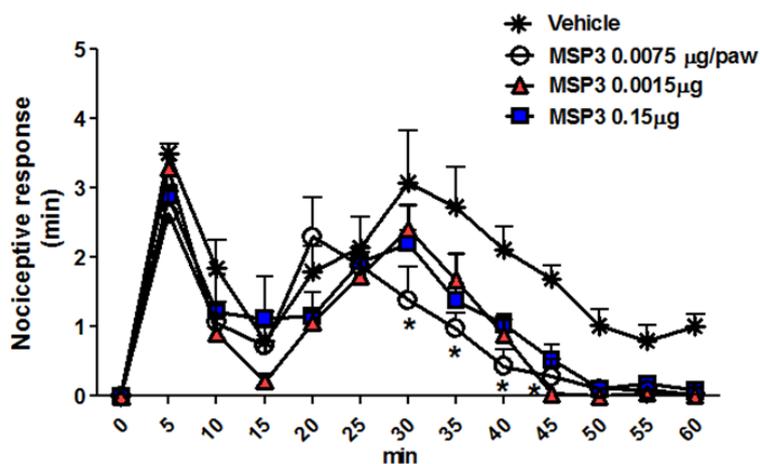

**Figure 4.** Effects of compound **1** (MSP-3) and capsaicin (CAPS) on H<sub>2</sub>O<sub>2</sub>-induced LDH release in human neuroblastoma cells. IMR-32 differentiated cells were pre-treated with compound **1** or capsaicin for 1 h (0.1-50 μM) prior to 300 μM H<sub>2</sub>O<sub>2</sub> for 15 hs. Data are reported as mean ± SEM. \*\*\*P < 0.01 vs CTRL. § and §§ P < 0.05 and P < 0.01 vs H<sub>2</sub>O<sub>2</sub>, respectively (ANOVA and Bonferroni post hoc test).

**Figure 5.** Morphological changes were observed under a contrast-phase microscopy (CPM, scale bar 100 mm, Original Magnification 100X, left panel); nuclear morphological changes of the cells were observed using a fluorescence microscopy (DAPI staining, right panel, scale bar 100 mm, Original Magnification 400X).

Based on the results obtained in the in vitro functional assay, we decided to investigate whether compound **1**, like capsaicin and other TRPV1 agonists, displayed any analgesic activity in vivo.

For this purpose, the formalin test of acute peripheral and inflammatory pain in mice was employed. Formalin-treated mice showed a typical nociceptive behavior characterized by an early, short lasting first phase (0–7 mins), followed by a quiescent period, and then a second, prolonged phase (15–60 mins) of tonic pain.<sup>20</sup> Test compound (concentrations ranging from 0.0075 to 0.15 μg/paw, 30 μL) was administered ten minutes before formalin treatment (1.25%, 30 μL) and lifting, favouring, licking, shaking and flinching of the injected paw were recorded as nociceptive responses (Figure 6).

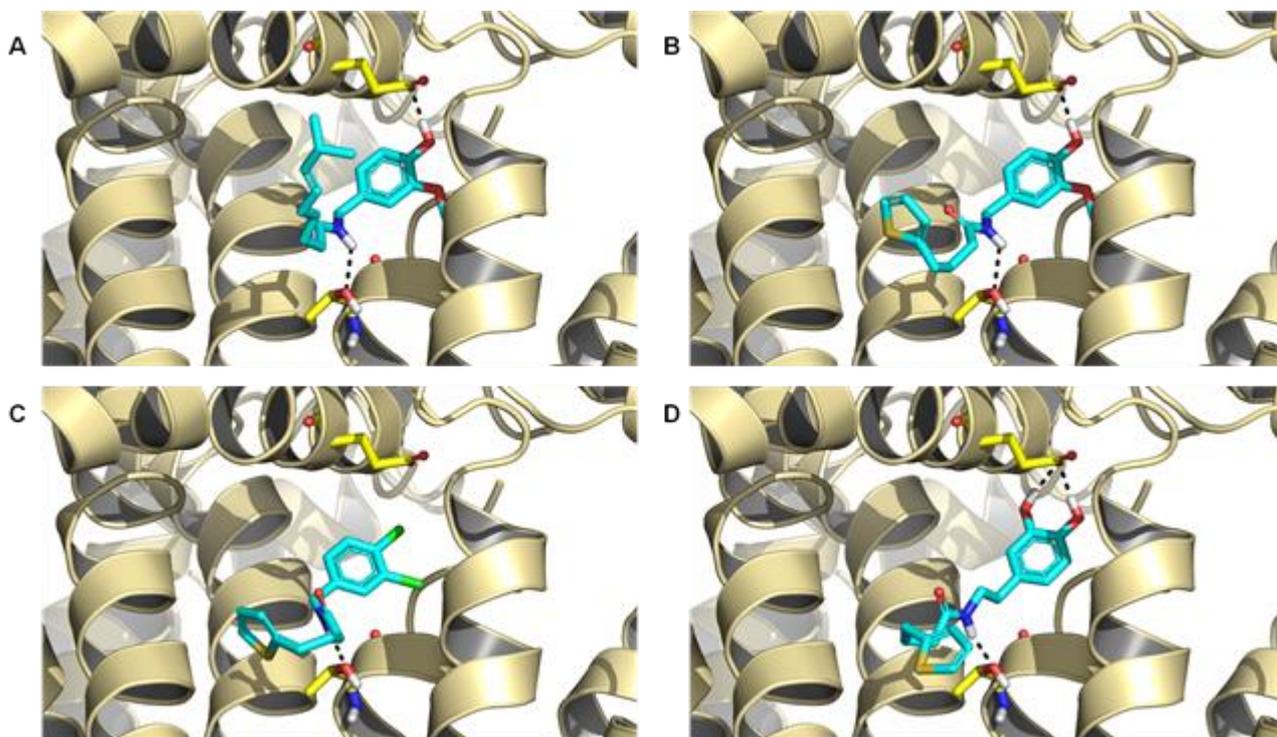

**Figure 6.** Formalin-treated mice showed a typical nociceptive behaviour characterized by an early, short lasting first phase, followed by a quiescent period, and then a second, prolonged phase of tonic pain. 10 mins before injection of formalin (1.25%, 30  $\mu$ L), mice received intrapaw administration of either vehicle or compound **1** (MSP-3, 0.0075, 0.015 and 0.15  $\mu$ g/paw, 30  $\mu$ L). The total time of the nociceptive response was measured every 5 mins and expressed in mins. The statistical significance was determined by two-way analysis of variance followed by a Turkey–Kramer post hoc test. \* indicate significant ( $P < 0.05$ ) differences vs formalin + vehicle-treated animals.

### Molecular modelling analysis

Starting from the 3D homology tetramer model of hTRPV1, kindly provided by Prof. Feng and collaborators,<sup>21</sup> we performed our molecular docking simulations in order to analyze the binding mode and the theoretical affinity of all synthesized compounds. In particular, as reported in Table S3 of the Supporting Information, we observed **1**, **2**, **3**, **6**, **9** and **10** as the most interesting ones, since they were associated with a Glide score (G-Score) similar or better to that of the reference agonist compound capsaicin. More specifically, **1**, **2** and **10** provided the best theoretical profile and the geometrical analysis of their best poses are reported in Figure 7.

Compounds **1**, **2** and **10** reproduced the binding mode of the reference TRPV1 agonist capsaicin, showing a pivotal conserved hydrogen bond (HB) between the amide nitrogen of the ligand and the hydroxyl group of Thr550. Moreover, capsaicin, **1** and **10** were further stabilized by additional HBs between the OH groups of the catechol moiety and Glu570.

**Figure 7.** Insight of the (A) capsaicin, (B) **1**, (C) **2** and (D) **10** TRPV1-temple complex showing the hydrogen bonds between the compound and the most involved residues of the protein binding pocket. TRPV1 and its interacting residues are shown, respectively, as light yellow cartoon and yellow carbon sticks; the ligands are represented as cyan carbon sticks. The hydrogen bonds are indicated as black dashed lines.

Based on the results obtained in the pharmacological experiments, we decided to further investigate compound **1**, since it resulted the most potent TRPV1 agonist. For this purpose, we analyzed the stability of [TRPV1·**1**] complex compared to that of capsaicin by means of 5 ns of molecular dynamics simulations (MDs). By analyzing both compounds, it is clear that capsaicin is conformationally more flexible with respect to **1**; such an evidence was further highlighted by the gyration radius study of both complexes, where the *extendedness* of capsaicin resulted higher if compared to that of **1** (Figure S1 of the Supporting Information). In terms of Root Means Square

Fluctuation (RMSF), calculated onto the protein side chains, we observed a comparable trend for both complexes (Figure S2 of the Supporting Information), as confirmed by the average obtained values for each TRPV1 residue ( $\text{RMSF}_{\text{caps}} = 2.07 \text{ \AA}$ ;  $\text{RMSF}_1 = 2.24 \text{ \AA}$ ).

During the MDs, we quantitatively evaluated the single components of the non binding interactions that are crucial for the ligand binding. Specifically, as reported in Figure S3 of the Supporting Information, **1** was well stabilized by several HBs with Tyr511, Thr550 and Glu570 and numerous hydrophobic interactions, especially with Ser512 and Phe591. By contrast, capsaicin binding resulted enhanced by a higher number of hydrophobic contacts to the detriment of HBs. Such an observation was in agreement with our thermodynamic analysis, where capsaicin was associated to a preponderant Van der Waals contribution for its binding affinity, while **1** was well stabilized in TRPV1 pocket especially through electrostatic interactions (Figure S4 of the Supporting Information).

Data obtained from functional assay (see Table 1) revealed that many of the newly synthesized compounds were able to activate TRPV1 channel, confirming our hypothesis that the 4-(thiophen-2-yl)butanoic acid amide moiety is a valuable scaffold for the design of a novel class of TRPV1 ligands. Compounds **1**, **3**, **5**, **9** and **10** are the most interesting compounds showing efficacy values higher than 50% and, in particular, derivative **1**, although less potent (compound **1**,  $\text{EC}_{50} = 870 \text{ nM}$  – capsaicin  $\text{EC}_{50} = 5.3 \text{ nM}$ ) behaved as a good TRPV1 agonist endowed with efficacy similar to that of capsaicin (79.6% and 78.6%, respectively). Concerning the cooperativity behaviour, compound **1** showed a Hill coefficient value  $> 1$  ( $1.095 \pm 0.056$ ), but slightly lower compared to that of capsaicin ( $1.25 \pm 0.09$ ); therefore, compound **1** displayed cooperativity, yet to lesser extent than capsaicin. In agreement with structure-activity relationships reported in the literature,<sup>1,9-10</sup> all active compounds possess a phenol moiety though placed at different distance from the amide functionality (see compounds **9**, **5**, and **10**). The natural substitution pattern, the vanillyl moiety, was still optimal for TRPV1 activity, but also 3,4-dichlorobenzyl group was tolerated furnishing a quite potent derivative (compound **2**,  $\text{EC}_{50} = 1.4 \text{ }\mu\text{M}$ ) although endowed with lower efficacy. On the other hand, the introduction of aliphatic

moieties in the amide head caused a considerable loss of binding ability. Cytotoxicity of compound **1** was evaluated in HaCaT cells by measuring LDH release. As shown in Figure 2A, the treatment with compound **1** (at concentrations ranging from 0.1 to 10  $\mu\text{M}$ ) did not cause any cytotoxic effect in HaCaT cells both at 24 hs and at 48 hs and similar results were obtained in the presence of capsaicin (Figure 2C). These results were confirmed also by Alamar Blu assay, where no differences in cell viability between control and cells treated with compound **1** (Figure 2B) or with capsaicin (Figure 2D) after 24 and 48 hs were observed. The protective role of compound **1** against oxidative stress on both HaCaT cells and differentiated human neuroblastoma (IMR-32) cells was then investigated and compared to that exerted by capsaicin. Normally, human body produces oxygen free radicals (OFR) and other reactive oxygen species (ROS) as by products in numerous physiological processes, primarily as a result of aerobic metabolism. ROS have important beneficial effects under regulated and homeostatic conditions but they are potentially dangerous when produced in excess, because increased oxidative stress can damage biomolecules (proteins, lipids, and DNA), often leading to many chronic diseases, such as cancer, aging and neurodegenerative disorders. Therefore, compounds endowed with antioxidant activity may have high therapeutic potential and in vitro cell culture studies can be very useful in assessing such properties. In HaCaT cells, as shown in Figure 3, the GO treatment induced a significant increase of HNE protein-adduct levels, effect prevented in a concentration-dependent manner by compound **1** pre-treatment. This antioxidant effect was also exhibited by the natural capsaicin, even if with lower efficacy since only the highest concentration (10  $\mu\text{M}$ ) was significantly effective. Additionally, in differentiated human neuroblastoma (IMR-32) cells the  $\text{H}_2\text{O}_2$  treatment induced a significant increase of LDH release, which reached the value of  $181.2 \pm 9.3\%$  vs controls (Figure 4). The pretreatment with MSP3 (0.1–50  $\mu\text{M}$ ), however, restored cell viability in a concentration-dependent fashion. In particular, highest concentrations of compound **1** (i.e. 10 and 50  $\mu\text{M}$ ) proved to be maximally effective, as LDH efflux into the medium amounted to  $150.7 \pm 4.1\%$  ( $P < 0.05$  vs  $\text{H}_2\text{O}_2$ ) and  $124.3 \pm 3.4\%$  ( $P < 0.01$  vs  $\text{H}_2\text{O}_2$ ), respectively. Interestingly, LDH release observed after treatment with 50  $\mu\text{M}$  concentration of compound **1** was not significantly

different from that observed in control slices, thus indicating that compound **1** completely reverted H<sub>2</sub>O<sub>2</sub> injury. Furthermore, preliminary results obtained by using rat brain cortical slices, an experimental model that maintains the cellular architecture of an intact brain, confirmed the neuroprotective effects of compound **1** (Figure S7 of the Supporting Informations).

In differentiated IMR-32 cells the natural TRPV1 agonist capsaicin reverted hydrogen peroxide-induced LDH release. Its effects, however, were not linearly correlated to the concentration used, but followed a U-shaped curve, typical of a hormetic-like effect. The efficacy window was very narrow, since 1 μM capsaicin was the only effective concentration while lower (0.1 μM) or higher (10-50 μM) concentrations were ineffective. Also in rat cortical slices, subjected to oxidative stress, capsaicin exerted neuroprotection according to a hormetic profile, which was still characterized by a very narrow efficacy window (i.e. 10 μM, see Supporting Informations). The hormetic or biphasic effect of capsaicin was already described in different experimental models,<sup>22-23</sup> and the mechanism underlying this phenomenon could rely on a longer-lasting refractory state of the receptors which might occur at concentration of 10-50 μM capsaicin, leading to a lack in the neuroprotective effects. Alternatively, we can hypothesize that TRPV1 receptor activation at the highest capsaicin concentration runs in parallel with the activation of other pathways leading to the suppression of the neuroprotection effect as net, final result. The ability of compound **1** to revert hydrogen peroxide-induced LDH release in a concentration-dependent fashion, along with its stronger antioxidant properties, makes this compound more interesting in terms of neuroprotection and for this reason its effects were further investigated.

Morphological analysis of IMR-32 cells performed at phase-contrast microscopy showed that H<sub>2</sub>O<sub>2</sub> caused grade 2 sign of cytotoxicity since about 50% of the cells were round and devoid of intracytoplasmic granules (see Figure 5). Compound **1** significantly attenuated changes caused by H<sub>2</sub>O<sub>2</sub> injury as the morphology of IMR-32 cells treated with the highest concentration of the drug was of grade 0 - 1, i.e. low percentage (20%) of round, loosely attached cells and without

intracytoplasmic granules. Furthermore, DAPI staining assay showed that DNA fragmentation detected after H<sub>2</sub>O<sub>2</sub> exposure was reverted by compound **1** pre-treatment (10 and 50 μM).

Lastly, based on the results obtained in in vitro assay, we decided to investigate whether compound **1**, like other TRPV1 agonists and capsaicin, exhibited any analgesic activity in vivo by using the formalin test of peripheral acute and inflammatory pain. Intriguingly, the administration of compound **1** in the range of concentrations used displayed a slight, but significant antinociceptive effect by reducing the second phase of the nocifensive behavior induced by formalin treatment (see Figure 6). The effect on the late phase of the formalin, that involves a spinal sensitization, paves the way to investigate this compound in a model of the persistent pain in which several plastic changes occur at spinal and supraspinal levels.

In agreement with the experimental observations, the molecular modeling analysis allowed us to rationalize the better profile of compounds **1**, **2**, **3**, **6**, **9** and **10**, since also docking simulations showed them as the most promising ones. In particular, as already reported in a recent work,<sup>24</sup> their binding affinity was found to be strictly related to pivotal hydrogen bonds between the vanillyl head and amide neck with residues Glu570 and Thr550 of TRPV1 channel, respectively.

By means of our MDs, we compared the reference TRPV1 agonist capsaicin with the most potent compound **1** both geometrically and thermodynamically, thus detecting similar profiles, according to **1** high efficacy *versus* TRPV1.

## CONCLUSIONS

In this study, we have investigated a novel class of chemically stable TRPV1 ligands characterized by the 4-(thiophen-2-yl)butanoic acid amide moiety, starting from the working hypothesis that the long unsaturated side chain of capsaicin could be replaced by a moderately flexible aromatic backbone. Several compounds were found to activate TRPV1 channels, and in particular, derivatives **1** and **10** behaved as TRPV1 agonists endowed with good efficacy as compared to capsaicin. Moreover, compound **1** has turned out to prevent in a concentration-dependent fashion the generation

of HNE protein-adducts in HaCaT cells and so to protect keratinocyte cell line by OS damage with more efficacy than the reference compound capsaicin. According to this result, compound **1** dose-dependently prevented also the damage caused by H<sub>2</sub>O<sub>2</sub> in differentiated human neuroblastoma cell line as well as rat cortical slices, by completely reverting OS injury at the highest concentration tested and hence showing high neuroprotective effect. On the contrary, capsaicin neuroprotection was limited by a narrow efficacy window, being 1 μM (IMR-32 cells) or 10 μM (rat cortical slices) the only active concentrations. In vivo results have also highlighted the slight, but significant antinociceptive effect of compound **1** in the second phase of the nocifensive response. Finally, cytotoxicity and cell viability assays confirmed the safe biological profile of compound **1**. Molecular modeling data resulted in agreement with the experimental observations, thus structurally rationalizing the binding mechanism of the most potent **1**.

These results indicate that our novel compounds may represent useful leads for the future development of new TRPV1 ligands and/or of small molecules endowed with protective effects against oxidative stress and with analgesic activity.

## **METHODS**

**Chemistry.** All starting materials, reagents and solvents were purchased from common commercial suppliers and were used as received unless otherwise indicated. Organic solutions were dried over anhydrous sodium sulfate and concentrated with a Büchi rotary evaporator R-110 equipped with KNF N 820 FT 18 vacuum pump. Melting points were determined on a Kofler apparatus (K) or using a Gallenkamp melting point apparatus (G) and are uncorrected. <sup>1</sup>H-NMR and <sup>13</sup>C-NMR spectra were recorded in the indicated solvent at 25 °C on a Bruker Advance DPX400 or 300MHz spectrometer and chemical shifts were expressed as δ (ppm). The chromatography-mass spectrometry (LC-MS) system consisted of a Triple Quad™ System API 3200 or of an Agilent 1100 series liquid chromatograph system including a 1100 MSD model VL benchtop mass spectrometer with API-ES interface, a binary high-pressure gradient pump (0.4 mL/min low flow rate, employing a binary

solvent system of 95/5 methanol/water), and a solvent degassing unit. Nitrogen (purity 99.995%) was used as nebulizer and drying gas. UV detection was monitored at 254 nm. Mass spectra were acquired in positive or negative mode scanning over the mass range  $m/z$  of 150-1500. IR spectra were recorded on a Perkin-Elmer FT-IR Spectrum TWO (Nujol dispersion or  $\text{CHCl}_3$  solution). The structures of final compounds were unambiguously assessed by  $^1\text{H-NMR}$ ,  $^{13}\text{C-NMR}$ , MS and/or IR. All compounds were checked for purity by TLC on Merck 60 F<sub>254</sub> silica plates. For column chromatography, Merck 60 silica gel, 230-400 mesh, was used. Final products were purified by a Biotage flash chromatography system with columns 12.25 mm, packed with KP-Sil, 60A, 32-63  $\mu\text{M}$ . Compound purity was assessed by elemental analysis on a Perkin-Elmer elemental apparatus model 240 for C, H, N, and the data are within  $\pm 0.4\%$  of the theoretical values. All the tested compounds possessed a purity  $>95.0\%$ .

**General procedure for the synthesis of final amides 1-4, 6-13, and 15-18.** To a solution of the appropriate amine (1.5 eq., or the appropriate amine hydrochloride, 1.5 eq., and trimethylamine, 2.0 eq.) in dry DCM (10 mL), at room temperature and under nitrogen atmosphere, a solution of the 4-(thien-2-yl)butanoic acid (1.0 eq.) in dry DCM (2.0 mL), solid HOBt (1.2 eq.) and a solution of CMC (1.5 eq.) in dry DCM (3.0 mL) were added respectively. The mixture was stirred at rt for 24 hs. After this time, the solvent was washed twice with a 5%  $\text{NaHCO}_3$  solution and twice with a saturated  $\text{NH}_4\text{Cl}$  solution. The collected organic layers, dried on anhydrous  $\text{Na}_2\text{SO}_4$ , were concentrated and the crude compound purified by flash chromatography on silica gel with the appropriate eluent mixtures.

***N*-(4-hydroxy-3-methoxybenzyl)-4-(thiophen-2-yl)butanamide 1.** Eluent:  $\text{CHCl}_3/\text{MeOH} = 48/2$ . Yield 60% as yellow oil. IR (Nujol): 3287, 1645  $\text{cm}^{-1}$ .  $^1\text{H-NMR}$  (300 MHz)  $\text{CDCl}_3$   $\delta$  (ppm): 7.04 (dd, 1H,  $J = 4.0$  Hz,  $J = 1.0$  Hz.), 6.9-6.6 (m, 5H), 4.26 (d, 2H,  $J = 5.6$  Hz), 3.78 (s, 3H), 2.80 (t, 2H,  $J = 7.5$  Hz.), 2.19 (t, 2H,  $J = 7.0$  Hz), 2.01-1.91 (m, 2H).  $^{13}\text{C-NMR}$  (300 MHz)  $\text{CDCl}_3$   $\delta$  (ppm): 172.5, 146.7, 145.1, 144.1, 130.0, 126.7, 124.5, 123.2, 120.7, 114.4, 110.7, 55.9, 43.6, 35.5, 29.0, 27.4. MS

(E.I.)  $m/z$ : 305  $[M]^+$  (22), 137 (100). Anal. calcd. for  $C_{16}H_{19}NO_3S$  (MW 305.39): C, 62.93%; H, 6.27%; N, 4.59%. Found: C, 62.91%; H, 6.28%; N, 4.58%.

**Synthesis of *N*-(4-hydroxybenzyl)-4-(thiophen-2-yl)butanamide 5.** A solution of 4-(thien-2-yl)butanoic acid (1.0 eq.), 4-methoxybenzylamine (1.5 eq.) and *N*-hydroxybenzotriazole (HOBt) (1.2 eq.) in dry DCM (2.5 mL) was cooled at 0 °C and stirred under  $N_2$  atmosphere for 15 mins. Thereafter, a solution of 1-cyclohexyl-3-(2-morpholinoethyl)carbodiimide (CMC) (1.5 eq.) in dry DCM (3.5 mL) was added dropwise. The mixture was stirred at rt for 24 hs, then the solvent was washed twice with a 5%  $NaHCO_3$  solution, then twice with a saturated  $NH_4Cl$  solution and finally once with brine. The collected organic layers, dried on anhydrous  $Na_2SO_4$ , were concentrated and the crude compound used in the next reaction without further purification. To a solution of crude compound (1.0 eq.) in dry toluene, heated at 50 °C for 15 mins, was added  $BBr_3$  (4.0 eq.) and the mixture was stirred at 100 °C for 1 h. Afterward, the reaction mixture was allowed to reach room temperature, then cooled to 0 °C and cautiously treated dropwise with  $H_2O$ . The organic layer was separated and washed with  $NaCl$  saturated solution and 2 N  $NaOH$  (3-4 times). The alkaline aqueous phase was treated with concentrated  $HCl$  to pH 2 and extracted with  $Et_2O$ . The dried and filtered organic layer afforded the pure compound after evaporation of solvent.

Yield 25% as brown solid. Mp 105.5 °C (G).  $^1H$ -NMR (300 MHz)  $CDCl_3$   $\delta$  (ppm): 6.99 (m, 3H), 6.8-6.5 (m, 4H), 6.10 (br s, 1H), 4.20 (d, 2H,  $J = 5.4$  Hz), 2.75 (t, 2H,  $J = 7.0$  Hz), 2.15 (t, 2H,  $J = 7.7$  Hz), 1.90 (m, 2H).  $^{13}C$ -NMR (300 MHz)  $CDCl_3$   $\delta$  (ppm): 173.2, 156.1, 144.0, 129.2 (x2), 129.1, 126.8, 124.6, 123.2, 115.8 (x2), 43.3, 35.5, 29.1, 27.5. MS (E.I.)  $m/z$ : 275  $[M]^+$  (100). Anal. calcd. for  $C_{15}H_{17}NO_2S$  (MW 275.37): C, 65.43%; H, 6.22%; N, 5.09%. Found: C, 65.33%; H, 6.24%; N, 5.10%.

**Synthesis of 2-(4-(thiophen-2-yl)butanamido)ethanesulfonic acid 14.** A solution of 2-aminoethanesulfonic acid hydrochloride (1.1 eq.) and triethylamine (1.4 eq.) in dry DMF (3 mL) was added to a mixture of 4-(thiophen-2-yl)butanoic acid (1.0 eq.) and 2-ethoxy-1-ethoxycarbonyl-1,2-

dihydroquinoline (EEDQ) (1.4 eq.) in dry DMF (1.5 mL) and the mixture heated at 90 °C, under N<sub>2</sub>, to obtain a clear solution. After cooling to room temperature, the solution was stirred for additional 30 mins and then, poured in cold diethyl ether (15 mL) and left to 4 °C overnight. The mixture was decanted and the resinous residue dried under vacuum. The resulting solid was then added to a stirred solution of HCl in methanol (0.85 M, 4.0 eq.) at room temperature. After stirring at rt for 24 hs, the suspension was partitioned between chloroform and NaHCO<sub>3</sub> saturated solution. The aqueous phase was acidified to pH 6.5 with 1 M HCl and again extracted with chloroform. The organic layers were dried and concentrated to afford a crude material, which was purified by flash chromatography (CHCl<sub>3</sub>/MeOH 48/2) to give a brown oil (yield 15%).

IR (Nujol): 3500, 1650 cm<sup>-1</sup>. <sup>1</sup>H-NMR (300 MHz) CDCl<sub>3</sub> δ (ppm): 7.09 (dd, 1H, *J* = 5.1, *J* = 1.1 Hz), 6.90 (dd, 1H, *J* = 5.1, *J* = 3.4 Hz), 6.79 (m, 1H), 3.70 (m, 2H), 2.98 (m, 2H), 2.85 (m, 2H), 2.22 (t, 2H, *J* = 5.1 Hz), 1.98 (m, 2H). <sup>13</sup>C-NMR (300 MHz) CDCl<sub>3</sub> δ (ppm): 171.5, 141.1, 126.1, 126.0, 124.0, 41.9, 40.1, 31.9, 29.7, 29.3. Found: C, 43.25%; H, 5.47%; N, 5.03%.

**Ligand preparation.** For ligand preparation, the 3D structures of all the studied compounds were generated with the Maestro Build Panel into the graphic interface Maestro Schrödinger 10.1.<sup>25</sup> Considering that for an in silico experiment a 3D structure database requires an efficient generation of reasonable, energetically minimized conformations,<sup>26</sup> all ligands were also energy minimized in the absence of the receptor with the OPLS\_2005 force field<sup>27</sup> as implemented in the Schrödinger suite, and the lowest energy conformations were used as starting points for the docking simulations.

**Target optimization.** An inevitable prerequisite for generating a structure-based model is the knowledge about the ligand-target interaction,<sup>28</sup> including the availability of the 3D structure of the target. Because of the unavailability of a human model of TRPV1, we adopted the 3D coordinates of the model obtained by homology modelling<sup>21</sup> and kindly provided by Prof. Feng.

The preparation procedure of the complex started with “Protein Preparation Wizard”<sup>29</sup> function in Maestro. Hydrogen atoms were added and, finally, the energy minimization calculation was performed using OPLS\_2005 force field until the RMSD of all heavy atoms within 0.3 Å.

**Docking simulations.** Docking studies of **1-18** towards TRPV1 model were performed by means of Glide software ver. 6.6.<sup>30</sup> The purpose of this method was to develop an exhaustive search in the space of the various positions, orientations, and conformations of each ligand compared to the target. A semi-flexible approach was considered: all flexible 3D ligands were sequentially docked into the binding pocket of the rigid receptors. For the target, using the Receptor Grid Generation panel with the default options, a cubic box of 27000 Å<sup>3</sup> was defined as binding region, generating the centroid of the most important residues involved in binding of several TRPV1 compounds, as Capsaicin.

For each docking run, we recorded a maximum of 10 poses per ligand; Glide SP protocol was used and the best docked poses for each ligand were selected considering the most negative G-score value.

**Molecular dynamics simulations.** Capsaicin and the most interesting TRPV1 agonist **1** were submitted to molecular dynamic simulations (MDs) in order to rationalize the physical basis of the complexes; in fact, MD simulations contain explicit treatment of water and intrinsic receptor flexibility, capturing the dynamic nature of protein-ligand interaction.

The simulation was carried out under the following conditions: recording interval equal to 10 ps; 5 ns of simulation time at 300 K; pressure set to 1 bar; OPLS2005 as force field and TIP4P<sup>31</sup> water molecules. All simulations were performed by Desmond package<sup>32</sup> and “Simulation Interactions Diagram” panel was used as post-MD analysis tool for exploring protein-ligand interactions.

Desmond “Simulation event analysis” tool was used to monitor, over 5 ns, the Root Mean Square fluctuation (RMSF), calculated onto TRPV1 side chains, the global number of hydrogen bonds (HBs) and hydrophobic interactions established by the ligands with the enzyme, and the interaction energy, in terms of Van der Waals and electrostatic single contributions, of capsaicin and **1**.

The 3D Figures were obtained with PyMOL graphics and modeling package, version 1.7.<sup>33</sup>

**Procedure for TRPV1 channel assay.** HEK293 (human embryonic kidney) cells stably over-expressing recombinant human TRPV1 were grown on 100 mm diameter Petri dishes as mono-layers in minimum essential medium (EMEM) supplemented with nonessential amino acids, 10% foetal bovine serum, and 2 mM glutamine, and maintained at 5% CO<sub>2</sub> at 37 °C. Stable expression of channels was checked by quantitative PCR (data not shown). The effect of the substances on intracellular Ca<sup>2+</sup> concentration ([Ca<sup>2+</sup>]<sub>i</sub>) was determined by using Fluo-4, a selective intracellular fluorescent probe for Ca<sup>2+</sup>. On the day of the experiment, cells were loaded for 1 h at room temperature with the methyl ester Fluo-4-AM (4 μM; Invitrogen) in EMEM without foetal bovine serum, then were washed twice in tyroide's buffer (145 mM NaCl, 2.5 mM KCl, 1.5 mM CaCl<sub>2</sub>, 1.2 mM MgCl<sub>2</sub>, 10 mM D-glucose, and 10 mM HEPES, pH 7.4), resuspended in the same buffer, and transferred to the quartz cuvette of the spectrofluorimeter (Perkin-Elmer LS50B; Perkin-Elmer Life and Analytical Sciences, Waltham, MA, USA) under continuous stirring. [Ca<sup>2+</sup>]<sub>i</sub> was determined before and after the addition of test compounds (0.01-100 μM) by measuring cell fluorescence ( $\lambda_{EX}$  = 488 nm,  $\lambda_{EM}$  = 516 nm) at 25 °C. Curve fitting (sigmoidal dose-response variable slope) and parameter estimation were performed with GraphPad Prism® (GraphPad Software Inc., San Diego, CA). Potency was expressed as the concentration of test substance exerting half-maximal agonist effect (i.e., half-maximal increases in [Ca<sup>2+</sup>]<sub>i</sub>) (EC<sub>50</sub>). The efficacy of the agonists was first determined by normalizing their effect to the maximum Ca<sup>2+</sup> influx effect on [Ca<sup>2+</sup>]<sub>i</sub> observed with application of 4 μM ionomycin (Sigma). The values of the effect on [Ca<sup>2+</sup>]<sub>i</sub> in wild type HEK293 (i.e., not transfected with any construct) cells were taken as baseline and subtracted from the values obtained from transfected cells. Antagonist/desensitizing behaviour was evaluated against capsaicin (0.1 μM) for TRPV1, by adding the test compounds in the quartz cuvette 5 mins before stimulation of cells with agonists. Data are expressed as the concentration exerting a half-maximal inhibition of agonist-induced [Ca<sup>2+</sup>]<sub>i</sub> elevation (IC<sub>50</sub>), which was calculated again using GraphPad Prism® software. The effect on [Ca<sup>2+</sup>]<sub>i</sub> exerted by agonist alone was taken as 100%. Dose response curves

were fitted by sigmoidal regression with variable slope. Statistical analysis of the data was performed by analysis of variance at each point using ANOVA followed by the Bonferroni's test.

**Keratinocyte cell culture and treatment.** HaCaT cells were grown in Dulbecco's modified Eagle's medium High Glucose (Lonza, Milan, Italy), supplemented with 10% FBS, 100 U/mL penicillin, 100 µg/mL streptomycin and 2 mM L-glutamine as previously described.<sup>16</sup> Cells were incubated at 37 °C for 24 hs in 95% air/5% CO<sub>2</sub> until 80% confluency. HaCaT cells were pre-treated with compound **1** or capsaicin for 24 hs and 48 hs. The compound was dissolved in DMSO at a concentration of 10 µM as a stock solution. The stock was diluted to the required concentrations directly in the medium. The final concentration of DMSO in culture medium during compounds treatment did not exceed 0.1% (v/v). For HNE protein adducts determination, cells were collected or treated with glucose oxidase (1 U/mL, 1 h) and processed as described below, after treatment with compound **1** or capsaicin.

**Keratinocyte cellular viability.** Viability studies were performed at 24 and 48 hs after treatments by Alamar Blue (Resazurin sodium salt from Sigma) and LDH (EuroClone Milan, Italy) release assay. LDH release was measured enzymatically as previously described.<sup>15</sup> Prior to each assay, the cells were lysed with 0.1% (V/V) Triton X-100 in culture media for 30 mins at 37 °C to obtain a representative maximal LDH release as the positive control (100% toxicity). Alamar blue stock solution in phosphate buffered saline (pH 7.4, 1 mg/mL) was prepared to obtain final working concentration of 0.1 mg/mL in cell culture medium. Colour change of the redox indicator resazurin was measured at 544 nm (excitation) and 590 nm (emission) wavelengths to evaluate oxidized versus reduced forms of the reagent respectively.

**Western blot analysis.** Total cell lysates were extracted in solubilization buffer containing 50 mM Tris (pH 7.5), 150 mM NaCl, 10% glycerol, 1% Nonidet P-40, 1 mM EGTA, 0.1% SDS, 5 mM N-ethylmaleamide (Sigma-Aldrich Corp.), protease and phosphatase inhibitor cocktails (Sigma–Aldrich Corp.) as previously described.<sup>17</sup> Samples of 60 µg protein in 3X loading buffer (65 mM Tris base, pH 7.4, 20% glycerol, 2% sodium dodecyl sulfate, 5% β-mercaptoethanol and 1% bromophenol blue)

were boiled for 5 mins, loaded onto 10% sodium dodecyl sulphate–polyacrylamide electrophoresis gels and separated by molecular size. The gels were then electro-blotted onto nitrocellulose membranes which were then blocked for 1 h in Tris-buffered saline, pH 7.5, containing 0.5% Tween 20 and 5% milk. Membranes were incubated overnight at 4 °C with the primary antibody, goat anti-HNE (Millipore Corporation, Billerica, MA, USA). Membranes were then incubated with horseradish peroxidase-conjugated secondary antibody (anti-goat) for 1 h, and the bound antibodies were detected using chemiluminescence (BioRad, Milan, Italy). Images of the bands were digitized and the densitometry of the bands were performed using Image-J software.

**Differentiated human neuroblastoma cell line, reagents, and culture conditions.** Freely dividing IMR-32 cells (American Type Culture Collection, Rockville, MD, USA) were routinely cultured in 75-cm<sup>2</sup> flasks in 20-mL medium in 95% air and 5% CO<sub>2</sub> atmosphere at 37 °C and fed (i.e., refreshed medium) at 2-day intervals. The growth medium comprised of the Eagle Minimum Essential Medium supplemented with 2 mM L-glutamine, 10% heat-inactivated fetal bovine serum (FBS), 100 UI/mL penicillin and 0.01 mg/mL streptomycin. When confluent, the cells were detached by washing with 0.25% trypsin solution and 0.53 mM EDTA in phosphate-buffered saline preheated to 37 °C. The suspension was centrifuged (1250×g, 5 mins) and the cells were replated at 2.5×10<sup>5</sup> cells/mL. After 48 hs, cells were differentiated according to Rao & Kisaalita<sup>18</sup> by the addition of 10 μM of 5-bromo-deoxyuridine (BrdU). The differentiation medium was completely refreshed every 2 days for 2 weeks.

**Drug treatment and differentiated human neuroblastoma cell viability assessment.** To assess neuroprotective effects, IMR-32 differentiated cells were treated for 1 h with compound **1** or capsaicin (0.1-50 μM) and thereafter H<sub>2</sub>O<sub>2</sub> (300 μM) was added to the medium for 15 hs. Control cell cultures were treated with vehicle (DMSO 0.01%). Cell viability was determined by measuring LDH activity in cell supernatant (Cytotoxicity Detection Kit, Roche) and data expressed as the percentage of LDH released, assuming that of control cells 100%. Moreover, in order to register defects in integrity and cellular density undetected by the LDH assay, IMR-32 differentiated cells were examined by a phase-

contrast light microscope. The results were evaluated using the grade scale, described in USP 28 (United States Pharmacopeia edition 2005) (grades 0-4) for assessment of the cytotoxic potential of tested materials, as follows: grade 0 - none reactivity (discrete intracytoplasmic granules, no cell lysis); grade 1 - slight reactivity (no more than 20% of the cells are round, loosely attached and without intracytoplasmic granules; occasional lysed cells are present); grade 2 - mild reactivity (no more than 50 % of the cells are round and devoid of intracytoplasmic granules, no extensive cell lysis and empty areas between cells); grade 3 - moderate (up to 70% of cells are rounded or lysed); grade 4 - severe (nearly complete destruction of the cells). Finally, assessment of apoptosis based on nuclear morphology was performed using the 4',6-diamidino-2-phenylindole (DAPI) staining kit (Life Technologies Italia, Monza, Italy) according to the manufacturer's protocol, with slight modifications.<sup>20</sup> At the end of drug treatment, cells were rinsed with ice-cold PBS buffer and immediately fixed with 4% paraformaldehyde (30 mins, 25 °C) followed by three washings with PBS. PBS/Triton (0.2% v v<sup>-1</sup>) was then added (10 mins, 25 °C) and afterward cells were stained with DAPI. After washing again with distilled water, cells were placed on a slide for fluorescence microscopy with the anti-fade mounting medium 1,4-diazabicyclo octane in glycerol (DABCO) and examined by a reverse-phase microscope (Leica Microsystems, Wetzlar, Germany). Nuclei with fragmented and condensed DNA were scored as apoptotic cells.

**Rat brain slices and hydrogen peroxide-induced injury.** All animal care and experimental protocols conformed to the European Union Guidelines for the Care and the Use of Laboratory Animals (European Union Directive 2010/63/EU) and were approved by the Italian Department of Health (813/2015-PR). The experimental protocols used were already described.<sup>34-35</sup> Briefly, male Wistar rats (250-300 g; Charles River Italia, Calco, Italy) were killed by decapitation, the brain quickly removed and placed in artificial cerebrospinal fluid (ACSF) with the following composition (in mM): 120 NaCl; 2 KCl; 1 CaCl<sub>2</sub>; 1 MgSO<sub>4</sub>; 25 HEPES; 1 KH<sub>2</sub>PO<sub>4</sub> and 10 glucose, adjusted to pH 7.4 and previously bubbled with a 95% O<sub>2</sub>-5% CO<sub>2</sub> gas mixture for 20–30 mins. The cortex was dissected and cut into 400 µm-thickness slices by using a manual chopper (Stoelting Co., Wood Dale,

IL, USA). Slices were then transferred into 24-well culture plates containing 0.5 mL ACSF/well and left at room temperature (25 °C) for 60 mins in order to recover from slicing trauma. During this period, the medium was removed and replaced with fresh, oxygenated ACSF every 15 mins. Afterward, slices were treated with ACSF containing (or not, in case of controls) compound **1** or capsaicin (0.1-50 µM) for 60 mins at 30 °C. After this period, the medium with drugs was maintained and hydrogen peroxide (10 µM for 60 mins) was added to the medium at 30 °C in a water bath.

**Brain slices viability assays: MTT and tissue edema.** Slice viability assay was performed by the colorimetric [3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide] (MTT) method. In particular, slices were washed with ACSF, incubated with 0.5 mg/mL of MTT (300 µL in the same 24 multi-well) at 37 °C for 45 mins. Then slices were gently transferred in a 96 multi-well, added with 200 µL of DMSO and incubated for 30 mins at 37°C in a shaking plate. After incubation, 100 µL of supernatant were prelevated and the formazan product measured at 560 and 630 nm (OD560–OD630). Cell viability was expressed as a percentage of untreated cells or slices (controls). Statistical significance was assessed by using ANOVA (ordinary or repeated measures followed by Dunnett or Bonferroni post test) (GraphPad Prism version 5.04, GraphPad Software Inc., San Diego, CA, USA). In all comparisons, the level of statistical significance (P) was set at 0.05.

**Evaluation of antinociceptive activity in mice.** Male C57BL/6J mice, 8 weeks old (Harlan, Italy), were housed 5 per cage under controlled illumination (12:12 hs light:dark cycle; light on 06.00 hs) and standard environmental conditions (room temperature  $22 \pm 1$  °C, humidity  $60 \pm 10\%$ ) for at least 1 week before experimental use. Mouse chow and tap water were available ad libitum. The experimental procedures were in accordance with Italian and European regulations governing the care and treatment of laboratory animals (Permission no. 41/2007B). Animal care was in compliance with Ethical Guidelines of the IASP and European Community (E.C. L358/1 18/12/86) on the use and protection of animals in experimental research. All efforts were made to minimize animal suffering and to reduce the number of animals used. Formalin injection induces a biphasic stereotypical

nocifensive behaviour.<sup>36</sup> Nociceptive responses are divided into an early, short-lasting first phase (0–7 mins) caused by a primary afferent discharge produced by the stimulus, followed by a quiescent period and then a second, prolonged phase (15–60 mins) of tonic pain. Mice received formalin (1.25% in saline, 30µL) in the dorsal surface of one side of the hindpaw. Each mouse was randomly assigned to one of the experimental groups, placed in a Plexiglas cage and allowed to move freely for 30 mins. A mirror was placed at a 45° angle under the cage to allow full view of the hindpaws. Lifting, favouring, licking, shaking, and flinching of the injected paw were recorded as nociceptive responses. The duration of these noxious behaviors was monitored by an observer blind to the experimental treatment for periods of 0–10 mins (early phase) and 20–60 mins (late phase) after formalin administration. Groups of 6-8 animals per treatment were used with each animal being used for one treatment only. Mice received vehicle (5% DMSO in 0.9% NaCl) or different doses of compound **1** (0.0075, 0.015 and 0.15 µg/paw, 30 µl) administered 10 mins before the formalin or saline.

Miniato, 53100 Siena (Italy); phone, +39 577 234329; fax, +39 577 234333; E-mail, [antonella.brizzi@unisi.it](mailto:antonella.brizzi@unisi.it).

**Notes.** The authors declare no competing financial interest.

## **ACKNOWLEDGMENT**

Authors from the University of Siena wish to thank Sienabiotech S.p.A. (Sienabiotech Grant 2012) for financial support. S. M. would like to thank the Ministero dell'Istruzione, dell'Università e della Ricerca (MIUR, PRIN 2012, Prot. n° 2012WBSSY4\_001) for financial support and Regione Campania that funded this research under POR Campania FESR 2007-2013 – O.O. 2.1. (FarmaBioNet). G. C. was supported by the “Research grant entitled to the memory of Anna and Nini Barbieri”. Thanks are also due to Professor Zhiwei Feng for providing the starting 3D homology tetramer model of hTRPV1.

## **ABBREVIATIONS**

TRPV1, transient receptor potential vanilloid type-1; ClogP, calculated coefficient partition; tPSA, topological polar surface area; SAR, structure-activity relationship; HaCaT, human keratinocyte cell line; IMR-32, human neuroblastoma cell line; CMC, 1-cyclohexyl-3-(2-morpholinoethyl)carbodiimide; HOBt, 1-hydroxybenzotriazole; EDDQ, N-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline; DMF, dimethylformamide; HEK293, human embryonic kidney cell line; LDH, lactate dehydrogenase; GO, glucose oxidase; OS, oxidative stress; LOPs, lipid oxidation products; HNE, 4-hydroxy-2-nonenal; DAPI, 4',6-diamidino-2-phenylindole; HB, hydrogen bond; MDs, molecular dynamics simulations; RMSF, root means square fluctuation; OFR, oxygen free radicals; ROS, reactive oxygen species.
