36

37 Abstract

38

39 Objectives

40 The aim of this study was to examine the impact of transmitted drug resistance (TDR)

41 on response to first-line regimens with integrase strand transfer inhibitors (INSTI) or

- 42 boosted protease inhibitors (bPI).
- 43 Methods

44 From an Italian observational database (ARCA) we selected HIV-1 infected drug-naïve 45 patients starting 2 nucleoside reverse transcriptase inhibitors (NRTI) and either an 46 INSTI or a bPI, with available pre-ART resistance genotype. The endpoint was 47 virological failure (VF: plasma HIV-1 RNA >200 copies/ml after week 24,). WHO surveillance drug resistance mutations and the Stanford algorithm were used to classify 48 49 patients into three resistance categories: no TDR (A), TDR but fully-active ART 50 prescribed (B), TDR and at least low-level resistance to one or more prescribed drug 51 (C).

52 **Results**

53 We included 1,365 patients with a median follow-up of 96-weeks (IQR 54-110): 1,205

54 (88.3%) starting bPI and 160 (11.7%) INSTI. Prevalence of TDR was 6.1%, 12.5%,

55 0.5% and 0% for NRTI, NNRTI, bPI, and INSTI, respectively.

56 Cumulative Kaplan-Meier estimates for VF at 48-weeks were 11% (10.1-11.9) for the

- 57 bPI- and 7.7% (5.4-10) for the INSTI-group.
- In the INSTI-group, cumulative estimates for VF at 48-weeks were 6% (4-8) in resistance category A, 5% (1-10) in B and 50% (30-70) in C (p<0.001). Resistance category C (versus A, adjusted hazard ratio, aHR 12.6, 3.2-49.8, p<0.001) and nadir
- 61 CD4 (+100 cells/μL, aHR 0.6, 0.4-0.9, p=0.03) predicted VF. In the bPI-group, VF
- 62 rates were not influenced by baseline resistance.
- 63 Conclusions

64 Our data support the need of NRTI-resistance genotyping in patients starting an INSTI-

- 65 based first-line ART.
- 66
- 67

68 Introduction

69

Transmission of drug resistant HIV-1 is a well-known phenomenon detected in around 8% of newly diagnosed individuals in Europe, with significant differences depending on viral subtype, geographic area, risk group and migration timeline.¹⁻³ Transmitted drug resistance (TDR) is increasing in Southern and Eastern Africa, particularly to the antiretroviral class of non-nucleoside reverse transcriptase inhibitors (NNRTI), a cornerstone of recommended first-line antiretroviral therapy (ART) in these countries.⁴ TDR may significantly influence the outcome of ART,⁵⁻⁷ therefore drug resistance

testing is recommended for the choice of the first-line regimen in resource-rich
 countries.⁸⁻¹¹

79

The risk of virological failure was increased in patients harboring pre-treatment drug resistance to at least one of the prescribed drugs in NNRTI-based regimens, as compared with individuals without pre-treatment drug resistance, but not in patients with pre-treatment drug resistance and fully active ART.¹²

84

International panels currently recommend first-line ART regimens including integrase strand transfer inhibitors (INSTI) or boosted protease inhibitors (bPI), because of their efficacy and tolerability.⁹⁻¹¹ However, in the absence of resistance testing, some authors suggest to use bPI due to their higher genetic barrier compared with INSTI.⁸ Indeed, the influence of TDR on the efficacy of INSTI-based first-line regimens has not yet been established, due to the exclusion of individuals carrying TDR from clinical trials and the sparse data from observational cohorts.^{5,6,13-16}

92

The aim of this study was to examine the impact of TDR on response to first-line regimens in naïve patients starting INSTI-based 3-drug antiretroviral therapy. As a reference, we also analyzed the impact of TDR on the efficacy of boosted PI-based regimens.

97

99

Protease, reverse transcriptase and integrase genotype sequences from treatment-naïve
HIV-1 infected adults starting a first-line therapy including 2 nucleoside or nucleotide

⁹⁸ Methods

reverse transcriptase inhibitors (NRTI) plus 1 INSTI or 2 NRTI plus 1 bPI from January
2008 to June 2016 were selected from the Antiviral Response Cohort Analysis (ARCA),
an Italian multicenter virological and clinical database [http://www.dbarca.net],
including cases with at least 1 plasma HIV-1 RNA value after 24 weeks of follow up.
The database was approved by the local Ethics Committees and written informed
consent was obtained from all patients before participation. The study was performed in
accordance with the ethical guidelines of the Declaration of Helsinki (7th revision).

109

110 Plasma genotypic resistance was determined by Sanger's population sequencing using 111 commercially available or homebrew systems. TDR was defined as the detection of at least one mutation among those included in the WHO-recommended surveillance drug 112 resistance mutation (SDRM) list for NRTI, NNRTI, bPI¹⁷ and those included in the 113 114 Stanford HIVdb **SDRM** Worksheet for INSTI 115 [https://hivdb.stanford.edu/pages/SDRM.worksheet.INI.html]. The Stanford HIVdb 116 algorithm (version 8.4, https://hivdb.stanford.edu) was used to classify patients into three resistance categories:⁴ absence of TDR mutations (resistance category A), 117 presence of TDR mutations but use of a fully-active ART regimen (B), or presence of 118 119 TDR mutations and at least low-level resistance to at least one prescribed drug (C). 120 HIV-1 subtyping was available as automatically performed by BLAST upon sequence upload and further analyzed by phylogenetic analysis in case of <95% homology to the 121 122 pure subtype reference panel.

123

The primary outcome was virological failure, defined as a plasma HIV-1 RNA >200
copies/mL after week 24, ignoring treatment changes. Survival analysis, using KaplanMeier curves, was employed to estimate the probability of virological failure. Predictors
of virological failure were investigated using Cox regression models. All analyses were
performed using SPSS (version 22, IBM, Armonk, NY).

129

130 **Results**

131

A total of 1,365 patients were included, 1,205 (88.3%) treated with 2 NRTI plus 1 bPI
and 160 (11.7%) treated with 2 NRTI plus 1 INSTI. Baseline patients' characteristics
are shown in table 1. The main differences between the two treatment groups were a
higher baseline plasma HIV-1 RNA and lower baseline and nadir CD4 cells counts in

the bPI group. Patients in the INSTI group were cared more frequently in Southern Italy 136 137 and started therapy more recently. The most frequently prescribed INSTI was 138 raltegravir (RAL) (39%), followed by dolutegravir (DTG) (35%) and 139 elvitegravir/cobicistat (EVG/c) (26%). The most frequently used bPI was 140 lopinavir/ritonavir (LPV/r) (41%), followed by atazanavir/ritonavir (ATV/r) (30%) and 141 darunavir/ritonavir (DRV/r) (28%).

142

The overall prevalence of any TDR mutation was 18.4%, without differences between groups. NRTI, NNRTI, PI and INSTI resistance mutations were detected in 83 (6.1%), 171 (12.5%), 35 (2.6%) and 0 (0.0%) patients, respectively. While there was a similar prevalence of NRTI TDR in the two treatment groups, NNRTI TDR was more frequent in the bPI group (13.1% versus 8.1% in the INSTI group, p=0.043), whereas PI TDR was less frequent in the PI group (2.1% versus 6.3%, p=0.05).

149

During a median follow-up time of 96 weeks (IQR 54-110) virological failure occurred in 195 individuals in the PI-group and in 11 in the INSTI-group, with an estimated cumulative probability at 48 weeks of 11% (CI 95% 10.1-11.9) and 7.7% (CI 95% 5.4-10), respectively (p=0.01 by log-rank test).

154

In the INSTI group, resistance category C showed a significantly higher estimated 155 156 probability of 48-week virological failure (50%, 95% CI 30-70) versus A (6%, 95% CI 157 (4-8) and B (5%, 1-10) (p<0.001). By contrast, in the bPI group the estimated probability 158 of virological failure at 48 weeks was similar in three categories: category A 11% (95% 159 CI 10-12), B 12% (95% CI 10-14) and C 9% (95% CI 5-13) (p=0.390) (Fig.1). In the 160 INSTI group, but not in the PI group, resistance category C (versus A, adjusted hazard ration, aHR 12.6, 3.2-49.8, p<0.001) and nadir CD4 (+100 cells/µL higher, aHR 0.6, 161 0.4-0.9, p=0.03) independently predicted virological failure. In the PI group, in a 162 163 multivariable model adjusting for gender, nationality, TDF/FTC use, viral subtype, type of bPI and TDR to NRTI, independent predictors of virological failure were AZT/3TC 164 use (aHR 2.3, CI 95% 1.4-3.9, p=0.002), calendar year (per 1 year more recent, aHR 165 0.9, CI 95% 0.8-0.9, p=0.04) and LPV/r use (versus DRV/r, aHR 1.4, CI 95% 1.0-2.0, 166 p=0.03). 167

168

169 Eleven patients, mostly (9/11) harboring viral subtype B, experienced virological failure 170 in the INSTI group: 8 were on treatment with RAL, 2 with DTG and 1 with EVG/c. At 171 failure, plasma HIV-1 RNA ranged between 210 and 213,200 copies/mL and higher 172 values were detected in patients with lower baseline CD4 counts. Three of the 11 failing 173 INSTI carried TDR to NRTI: 2 M41L and 1 M184V, while none carried resistance to 174 INSTI. Seven patients changed antiretroviral therapy after virological failure, with 6 175 patients switching to a bPI-based regimen. Among those that continued the previous 176 regimen, 3 reached virological re-suppression at the subsequent visit and 1 was lost to 177 follow up.

178

179 Discussion

180

181 The key finding of this study is the impact of pre-treatment HIV-1 drug resistance on 182 the risk of virological failure in patients initiating ART with 2 NRTI plus INSTI. 183 Despite the small number of cases, the magnitude of this effect was very relevant, with 184 a more than 10-fold higher adjusted hazard of virological failure as compared to patients 185 without TDR. To our knowledge, this is the first report showing a significant impact of 186 TDR to NRTI on the activity of first-line regimens with 2 NRTI plus INSTI, the current 187 standard of care of first-line ART. Indeed, previous observational studies on the influence of TDR did not include INSTI-based regimens and clinical trials with INSTI 188 excluded patients with TDR.^{1,2,5,13,18,19} Interestingly, in the same group, TDR not 189 affecting the activity of the prescribed drugs did not show any impact on virological 190 191 efficacy. This finding is reassuring, suggesting that even in the presence of TDR, 192 INSTI-based first-line regimens are effective when fully active accompanying drugs are 193 selected based on the resistance test result.

194

The overall prevalence of TDR in this cohort was 18.4%, higher than usually reported 195 in European cohorts, and was primarily driven by NNRTI resistance.¹⁻³ This could be 196 197 explained by the fact that, detection of TDRmay have advised to use high-genetic 198 barrier bPI therapy, resulting in an overestimate of TDR in the case file. In addition, 199 bPI-based regimens were preferentially prescribed to more challenging patients, such as 200 those with higher baseline viral load and lower CD4 counts, possibly explaining at least 201 in part the higher virological efficacy of INSTI-based as compared with PI-based 202 regimens observed here. The relatively long period of observation (2008-2016) may

203 also explain some imbalance observed between the two treatment groups reflecting drug 204 availability over time. In the PI-group, AZT/3TC and LPV/r use were associated to 205 more frequent virological failure, suggesting a crucial role of their lower tolerability and 206 efficacy. 207 208 The main limitations of this study are the retrospective nature, the small number of 209 patients treated with INSTIs and the relatively limited sample size in the INSTI 210 treatment groups, which did not allow a sufficient power to detect differences among 211 drugs with different genetic barrier. Future analyses including a larger and balanced 212 INSTI group are necessary to confirm our findings and clarify whether NRTI TDR has 213 a different impact on virological efficacy using different types of INSTI. 214 215 In conclusion, our findings support the need of pre-treatment drug resistance testing to 216 NRTI in order to optimize antiretroviral therapy in patients starting first-line INSTI-217 based regimens. 218 219 Acknowledgments 220 221 We thank the patients sharing their data, the ARCA clinical and laboratory units and the 222 ARCA Scientific Board. ARCA was supported by unconditional educational grants 223 from ViiV Healthcare, Gilead Sciences, Janssen, Hologic, MSD, Bristol-Myers Squibb, 016 224 Siemens Healthineers. 225 226 Funding 227 This study was conducted as part of our routine work. 228 229 **Transparency declarations**
